<b>Abstract:</b>	<p>Abstract. This study compared Sb<sub>2</sub>Se<sub>3</sub> material in the form of commercial polycrystalline bulk, sputtered thin film and homemade polycrystalline material using laser desorption ionisation (LDI) time of flight mass spectrometry with quadrupole ion trap mass spectrometry. It also analysed the stoichiometry of the SbmSen clusters formed. The results showed that homemade Sb<sub>2</sub>Se<sub>3</sub> bulk was more stable compared to thin film; its mass spectra showed the expected cluster formation. The use of materials for surface-assisted LDI (SALDI), i.e., graphene, graphene oxide and C60, significantly increased the mass spectra intensity. In total, nineteen SbmSen clusters were observed. Six novel, high-mass clusters—Sb<sub>4</sub>Se<sub>4</sub><sup>+</sup>, Sb<sub>5</sub>Se<sub>3-6</sub><sup>+</sup> and Sb<sub>7</sub>Se<sub>4</sub><sup>+</sup>—were observed for the first time when using paraffin as a protective agent.</p>

## 39 Introduction

40  
41  
42  $\text{Sb}_2\text{Se}_3$ , which is known in nature as the mineral antimonselite. The crystal and  
43 electronic structure of antimony selenide as well as its vibrational properties were  
44 previously determined [1-4]. Generally, the  $\text{Sb}_m\text{Se}_n$  system is an important member of  
45 chalcogenide materials. Under typical experimental conditions of chalcogenide glass  
46 synthesis, the glass-forming region in the  $\text{Sb}_m\text{Se}_n$  system is limited to rather low  
47 antimony content (up to 30%), and smaller glass batches often face phase separation  
48 problems [5-7]. On the other hand, it is possible to fabricate amorphous,

1 stoichiometric and thin  $\text{Sb}_2\text{Se}_3$  films by physical vapour deposition techniques such as  
2  
3 radio-frequency magnetron sputtering [8] or thermal evaporation [9]. Moreover,  
4  
5  $\text{Sb}_2\text{Se}_3$  forms stable glasses and amorphous thin films with other glass-forming  
6  
7 selenides like  $\text{GeSe}_2$  [10-13]. Today,  $\text{Sb}_m\text{Se}_n$  materials, especially in the form of thin  
8  
9 films, have been widely studied as amorphous thin films of  $\text{Sb}_2\text{Se}_3$  for memory  
10  
11 switching application [14-15], as glass-ceramic or antimony selenide thin films for  
12  
13 solar cells [16-20], as  $\text{Sb}_2\text{Se}_3$  anode for lithium, and sodium batteries [21-22].

20 In a previous article [23], we examined the formation of clusters produced by  
21  
22 laser ablation from mixtures of Sb and Se elements in different ratios. We observed 24  
23  
24  $\text{Sb}_m\text{Se}_n$  clusters that were generated from metal surface of common target. In this  
25  
26 study, we would like to compare the stoichiometry of clusters formed by laser  
27  
28 desorption ionisation (LDI) from  $\text{Sb}_2\text{Se}_3$  materials in the form of commercial  
29  
30 polycrystalline bulk, thin film, and homemade polycrystalline material to the clusters  
31  
32 generated by laser ablation synthesis (LAS) from the mixtures of elements (antimony  
33  
34 and selenium). Additionally, in order to evaluate the influence of various surfaces on  
35  
36 cluster formation, some other materials that act as surface-assisted LDI (SALDI)  
37  
38 matrices (graphene [G], graphene oxide [GO] and fullerene [ $\text{C}_{60}$ ]) were used. Since  
39  
40 paraffin (as a protective agent) was found to increase the intensity of chalcogenide  
41  
42 high mass clusters [24], we also studied the assistance of paraffin in detail.

## 56 **Experimental**

### 57 *Chemicals*

1 Polycrystalline  $\text{Sb}_2\text{Se}_3$  was purchased from Sigma-Aldrich (St. Louis, MO, USA).  
2  
3  
4 Homemade polycrystalline  $\text{Sb}_2\text{Se}_3$  was synthesised using high-purity elements (Sb  
5  
6 and Se of 99.999% purity). Acetonitrile, G, GO and  $\text{C}_{60}$  were purchased from  
7  
8 Sigma-Aldrich (Steinheim, Germany). Parafilm was purchased from Bemis NA  
9  
10 (Neenah, Wis., USA). Red phosphorus was obtained from Riedel de Haën (Hannover,  
11  
12 Germany) and was purified via sublimation in a nitrogen atmosphere. Water was  
13  
14 double distilled using a quartz apparatus from Heraeus Quarzschmelze (Hanau,  
15  
16 Germany). All other reagents were of analytical-grade purity. Amorphous  $\text{Sb}_2\text{Se}_3$  thin  
17  
18 films were fabricated by radio-frequency magnetron sputtering using an MPE600S  
19  
20 (Plassys-Bestek, France) multichamber physical vapour deposition system. For the  
21  
22 depositions, single crystalline silicon <100> substrates and a polycrystalline  $\text{Sb}_2\text{Se}_3$   
23  
24 sputtering target (99.999%, ALB Materials, USA) were employed. The experimental  
25  
26 details of thin film deposition are provided elsewhere [8]. No Bragg peaks were  
27  
28 detected in the X-ray diffraction patterns of deposited thin films, data that confirm  
29  
30 their amorphous state.

#### 45 *Mass spectrometry*

46  
47 AXIMA Resonance and AXIMA CFR mass spectrometers, both from Kratos  
48  
49 Analytical Ltd. (Manchester, UK), coupled with a quadrupole ion trap and  
50  
51 time-of-flight detection, were used to record mass spectra in both positive and  
52  
53 negative ion modes. Both instruments were equipped with a nitrogen laser (337 nm),  
54  
55 and the laser repetition rate was set to 5 Hz with a pulse time width of 3 ns.

23  
24 *amorphous  $Sb_2Se_3$  thin film*  
25  
26

27  
28 An agate mortar was used to pulverise the polycrystalline  $Sb_2Se_3$ ; the powder was  
29  
30 then suspended in acetonitrile (1 mg/ml). From the prepared suspensions, 10  $\mu$ L was  
31  
32 deposited on a MALDI target and dried in open air. The amorphous  $Sb_2Se_3$  thin film  
33  
34 was fixed on the target with a narrow piece of parafilm.

61  
62  
63  
64  
65

1 Ten  $\mu\text{L}$  of the  $\text{Sb}_2\text{Se}_3$  powder suspension (described above) was deposited on a  
2  
3 target and then covered with paraffin solution in xylene ( $1\text{ cm}^2$  of parafilm dissolved  
4  
5 in 1 ml xylene).  
6  
7

## 8 **Results and Discussion**

9

10 LDI of different materials was used to generate clusters while mass spectra were  
11  
12 recorded in both positive and negative ionisation modes by using a reflectron mass  
13  
14 analyser. This analysis revealed that a low number of clusters and low-intensity  
15  
16 spectra were produced in the negative ion mode. Therefore, the results obtained in the  
17  
18 positive ion mode are presented.

### 28 *Effect of laser energy on homemade $\text{Sb}_2\text{Se}_3$ polycrystalline material mass spectra*

29  
30

31 The effect of laser energy on intensity of clusters formed is shown in Figure 1. The  
32  
33 high-intensity clusters were observed in the 300-450  $m/z$  range; the intensities  
34  
35 heightened as the laser energy increased. However, some low-intensity clusters were  
36  
37 also observed in the 450-650 mass range (spectra not shown). This data indicates that  
38  
39 the homemade  $\text{Sb}_2\text{Se}_3$  polycrystalline material was rather easy to decompose even at  
40  
41 relatively low laser energy (140 a.u.). Detailed analysis of the homemade  $\text{Sb}_2\text{Se}_3$   
42  
43 polycrystalline material spectra is shown in Fig. S1A. In addition to  $\text{SbSe}_2^+$ ,  $\text{Sb}_2\text{Se}_n^+$   
44  
45 ( $n = 1, 2$ ) and  $\text{Sb}_3\text{Se}_n^+$  ( $n = 1-3$ ) clusters,  $\text{Sb}_m^+$  ( $m = 2-4$ ) clusters were also detected.

Comparison of experimental and theoretical isotopic patterns concerning  $\text{Sb}_3\text{Se}^+$  are  
provided in Fig. S1B. Overall, they showed good agreement.

1 *Effect of laser energy on thin film mass spectra*

2  
3 The effect of laser energy on thin film mass spectra (Fig. S2A) was different from  
4 that of homemade Sb<sub>2</sub>Se<sub>3</sub> polycrystalline material. At 140 a.u. laser energy, the cluster  
5 intensities reached their maxima. The mass spectra showed that the thin film was less  
6 stable against pulsed laser irradiation than the homemade Sb<sub>2</sub>Se<sub>3</sub> polycrystalline  
7 material. Further, the thin films were easier to ablate. An example of a thin film mass  
8 spectrum is shown in Figure 2. The thin film mass spectra showed similar clusters to  
9 those formed from the homemade Sb<sub>2</sub>Se<sub>3</sub> polycrystalline material. However, the  
10 Sb<sub>3</sub>Se<sub>3</sub><sup>+</sup>, SbSe<sub>2</sub><sup>+</sup>, Sb<sub>m</sub><sup>+</sup> (*m* = 2-4), Sb<sub>2</sub>Se<sub>n</sub><sup>+</sup> (*n* = 1, 2) and Sb<sub>3</sub>Se<sub>n</sub><sup>+</sup> (*n* = 1, 2) clusters  
11 were not observed. There was good agreement between the theoretical and  
12 experimental isotopic patterns concerning Sb<sub>2</sub>Se<sup>+</sup> cluster (Fig. S2B).

34 *Effect of laser energy on commercial Sb<sub>2</sub>Se<sub>3</sub> polycrystalline material mass spectra*

35  
36 Comparison of mass spectra generated from commercial Sb<sub>2</sub>Se<sub>3</sub> polycrystalline  
37 bulk at different laser energies is shown in Figure 3. Even at low laser energy (120  
38 a.u.), we observed several low-intensity clusters in the *m/z* range over 450. Fig. S3A  
39 shows the result of detailed mass spectra analysis concerning commercial Sb<sub>2</sub>Se<sub>3</sub>  
40 polycrystalline bulk material. Besides SbSe<sub>2</sub><sup>+</sup>, Sb<sub>2</sub>Se<sub>n</sub><sup>+</sup> (*n* = 1-4) and Sb<sub>3</sub>Se<sub>n</sub><sup>+</sup> (*n* = 1-5),  
41 Sb<sub>m</sub><sup>+</sup> (*m* = 3, 4) clusters were also noted. Comparison of experimental and theoretical  
42 isotopic patterns for the Sb<sub>2</sub>Se<sub>2</sub><sup>+</sup> cluster is provided in Fig. S3B; there was good  
43 agreement between the experiment with the theoretical model.

1 *Comparison of amorphous Sb<sub>2</sub>Se<sub>3</sub> thin film, commercial and homemade*  
2  
3 *polycrystalline Sb<sub>2</sub>Se<sub>3</sub> material mass spectra*  
4  
5

6 Figure 4 shows thin film, commercial and home-made polycrystalline Sb<sub>2</sub>Se<sub>3</sub>  
7  
8 material mass spectra that were measured using the same laser energy (120 a.u.). At  
9 this laser energy, the order of intensity was thin film, followed by homemade and  
10 finally commercial Sb<sub>2</sub>Se<sub>3</sub> polycrystalline material, data that indicate the stability of  
11 the three materials with respect to the increasing laser pulse. In the homemade  
12 polycrystalline Sb<sub>2</sub>Se<sub>3</sub> material and commercial Sb<sub>2</sub>Se<sub>3</sub> polycrystalline bulk material  
13 mass spectra, the most intensive cluster was Sb<sub>3</sub>Se<sup>+</sup>. Comparatively, in the thin film  
14 mass spectra, the Sb<sub>2</sub>Se<sup>+</sup> cluster was the strongest. The most intense cluster, observed  
15 in the thin film mass spectrum at 140–180 a.u. laser energy, was Sb<sub>3</sub>Se<sup>+</sup>. Additionally,  
16 the commercial Sb<sub>2</sub>Se<sub>3</sub> polycrystalline bulk produced more clusters.

36 *Special methods to enhance mass spectra intensity and produce higher-mass clusters*  
37

38  
39 *Enhancement of cluster intensity*  
40  
41

42 GO, G or C<sub>60</sub> were previously used as a matrix for SALDI mass spectrometry  
43 [25-27]. We examined whether these materials can increase the intensity of Sb<sub>2</sub>Se<sub>3</sub>  
44 mass spectra. Comparison of mass spectra for commercial Sb<sub>2</sub>Se<sub>3</sub> polycrystalline bulk  
45 and the same material deposited on the surface of GO, C<sub>60</sub> or G at the same laser  
46 energy (120 a.u.) is shown in Figure 6. GO, G and C<sub>60</sub> enhanced the intensity of the  
47 most of the signals present in mass spectra. GO was the most effective material for  
48  
49  
50  
51  
52  
53

62  
63  
64  
65

1 enhancing the mass spectra intensity (9-times greater intensity compared to simple  
2  
3 LDI), followed by C<sub>60</sub> and then G.  
4  
5

### 6 *Effect of paraffin*

7  
8

9 Comparison of commercial Sb<sub>2</sub>Se<sub>3</sub> polycrystalline bulk mass spectra with and  
10 without a paraffin cover at 160 a.u. laser energy is shown in Figure 7A, B and C. At  
11 the *m/z* range below 510, the cluster intensities produced solely by Sb<sub>2</sub>Se<sub>3</sub> was higher  
12 than when Sb<sub>2</sub>Se<sub>3</sub> was covered with paraffin. On the contrary, in the *m/z* range over  
13 510, the intensity of the clusters originating in Sb<sub>2</sub>Se<sub>3</sub> covered with paraffin was  
14 higher than that one produced by Sb<sub>2</sub>Se<sub>3</sub> alone. Furthermore, we detected the  
15 formation of new clusters beyond *m/z* 800 (Sb<sub>4</sub>Se<sub>4</sub><sup>+</sup>, Sb<sub>5</sub>Se<sub>3-6</sub><sup>+</sup> and Sb<sub>7</sub>Se<sub>4</sub><sup>+</sup>) from  
16 Sb<sub>2</sub>Se<sub>3</sub> covered with paraffin. Comparison of experimental and theoretical isotopic  
17 patterns for one newly identified Sb<sub>5</sub>Se<sub>6</sub><sup>+</sup> cluster is given in Fig. S4; the data showed  
18 good agreement between the experimental results and theoretical model. The results  
19 obtained indicate that paraffin acts as a protective agent to diminish fragmentation. It  
20 is not easy to explain the effect of paraffines, as it can be very complex. First, because  
21 particles of materials are covered with paraffin layer which is absorbing part of the  
22 laser energy, the fragmentation is diminished. In addition, similarly to those of Ag<sup>+</sup>  
23 adducts with paraffines [28], we observed here the formation of Sb<sub>*m*</sub>Se<sub>*n*</sub><sup>+</sup> cations  
24 adducts with paraffin (C<sub>4</sub>H<sub>10</sub>·Sb<sub>2</sub>Se<sub>3</sub><sup>+</sup> shown in Figure S5 A and C<sub>18</sub>H<sub>38</sub>·Sb<sub>3</sub>Se<sup>+</sup> shown  
25 in Figure S5 B). Such formation of charged adducts can also decrease the  
26 fragmentation. An overview of the Sb<sub>*m*</sub>, Se<sub>*n*</sub> and Sb<sub>*m*</sub>Se<sub>*n*</sub> clusters generated from all  
27 Sb<sub>2</sub>Se<sub>3</sub> forms and Sb:Se mixtures (1:1 or 1:10) [23] is provided in Figure 5.

## Conclusions

LDI with quadrupole ion trap time-of-flight mass spectrometry was used to characterise different  $\text{Sb}_2\text{Se}_3$  forms (commercial or home-made polycrystalline material or amorphous thin films). We showed that this technique is a powerful method to study the formation of binary  $\text{Sb}_m\text{Se}_n$  clusters. Homemade  $\text{Sb}_2\text{Se}_3$  polycrystalline material produced the lowest number of clusters during LDI. Commercial  $\text{Sb}_2\text{Se}_3$  polycrystalline bulk generated a higher number of detected  $\text{Sb}_m\text{Se}_n$  species. The amorphous  $\text{Sb}_2\text{Se}_3$  thin film was easily ablated. We demonstrated that GO, C60 or G are suitable materials for SALDI in order to enhance the mass spectra intensity of the clusters produced from  $\text{Sb}_2\text{Se}_3$  polycrystalline material. With the use of paraffin, some new clusters were detected in the high-mass part of the spectra.

## Acknowledgments

This work was funded with the support from the Czech Science Foundation (Projects No. 18-03823S).

1 **Abstract.** This study compared  $\text{Sb}_2\text{Se}_3$  material in the form of commercial  
2 polycrystalline bulk, sputtered thin film and homemade polycrystalline material using  
3 laser desorption ionisation (LDI) time of flight mass spectrometry with quadrupole  
4 ion trap mass spectrometry. It also analysed the stoichiometry of the  $\text{Sb}_m\text{Se}_n$  clusters  
5 formed. The results showed that homemade  $\text{Sb}_2\text{Se}_3$  bulk was more stable compared to  
6 thin film; its mass spectra showed the expected cluster formation. The use of materials  
7 for surface-assisted LDI (SALDI), i.e., graphene, graphene oxide and  $\text{C}_{60}$ ,  
8 significantly increased the mass spectra intensity. In total, nineteen  $\text{Sb}_m\text{Se}_n$  clusters  
9 were observed. Six novel, high-mass clusters— $\text{Sb}_4\text{Se}_4^+$ ,  $\text{Sb}_5\text{Se}_{3-6}^+$  and  $\text{Sb}_7\text{Se}_4^+$ —were  
10 observed for the first time when using paraffin as a protective agent.

## 39 Introduction

40  
41  
42  $\text{Sb}_2\text{Se}_3$ , which is known in nature as the mineral antimonselite. The crystal and  
43 electronic structure of antimony selenide as well as its vibrational properties were  
44 previously determined [1-4]. Generally, the  $\text{Sb}_m\text{Se}_n$  system is an important member of  
45 chalcogenide materials. Under typical experimental conditions of chalcogenide glass  
46 synthesis, the glass-forming region in the  $\text{Sb}_m\text{Se}_n$  system is limited to rather low  
47 antimony content (up to 30%), and smaller glass batches often face phase separation  
48 problems [5-7]. On the other hand, it is possible to fabricate amorphous,

1 stoichiometric and thin  $\text{Sb}_2\text{Se}_3$  films by physical vapour deposition techniques such as  
2  
3 radio-frequency magnetron sputtering [8] or thermal evaporation [9]. Moreover,  
4  
5  $\text{Sb}_2\text{Se}_3$  forms stable glasses and amorphous thin films with other glass-forming  
6  
7 selenides like  $\text{GeSe}_2$  [10-13]. Today,  $\text{Sb}_m\text{Se}_n$  materials, especially in the form of thin  
8  
9 films, have been widely studied as amorphous thin films of  $\text{Sb}_2\text{Se}_3$  for memory  
10  
11 switching application [14-15], as glass-ceramic or antimony selenide thin films for  
12  
13 solar cells [16-20], as  $\text{Sb}_2\text{Se}_3$  anode for lithium, and sodium batteries [21-22].  
14  
15  
16  
17  
18  
19

20 In a previous article [23], we examined the formation of clusters produced by  
21  
22 laser ablation from mixtures of Sb and Se elements in different ratios. We observed 24  
23  
24  $\text{Sb}_m\text{Se}_n$  clusters that were generated from metal surface of common target. In this  
25  
26 study, we would like to compare the stoichiometry of clusters formed by laser  
27  
28 desorption ionisation (LDI) from  $\text{Sb}_2\text{Se}_3$  materials in the form of commercial  
29  
30 polycrystalline bulk, thin film, and homemade polycrystalline material to the clusters  
31  
32 generated by laser ablation synthesis (LAS) from the mixtures of elements (antimony  
33  
34 and selenium). Additionally, in order to evaluate the influence of various surfaces on  
35  
36 cluster formation, some other materials that act as surface-assisted LDI (SALDI)  
37  
38 matrices (graphene [G], graphene oxide [GO] and fullerene [ $\text{C}_{60}$ ]) were used. Since  
39  
40 paraffin (as a protective agent) was found to increase the intensity of chalcogenide  
41  
42 high mass clusters [24], we also studied the assistance of paraffin in detail.

## 56 **Experimental**

### 57 *Chemicals*

1 Polycrystalline  $\text{Sb}_2\text{Se}_3$  was purchased from Sigma-Aldrich (St. Louis, MO, USA).  
2  
3 Homemade polycrystalline  $\text{Sb}_2\text{Se}_3$  was synthesised using high-purity elements (Sb  
4 and Se of 99.999% purity). Acetonitrile, G, GO and  $\text{C}_{60}$  were purchased from  
5  
6 Sigma-Aldrich (Steinheim, Germany). Parafilm was purchased from Bemis NA  
7  
8  
9  
10  
11  
12 (Neenah, Wis., USA). Red phosphorus was obtained from Riedel de Haën (Hannover,  
13  
14 Germany) and was purified via sublimation in a nitrogen atmosphere. Water was  
15  
16 double distilled using a quartz apparatus from Heraeus Quarzschmelze (Hanau,  
17  
18 Germany). All other reagents were of analytical-grade purity. Amorphous  $\text{Sb}_2\text{Se}_3$  thin  
19  
20 films were fabricated by radio-frequency magnetron sputtering using an MPE600S  
21  
22 (Plassys-Bestek, France) multichamber physical vapour deposition system. For the  
23  
24 depositions, single crystalline silicon <100> substrates and a polycrystalline  $\text{Sb}_2\text{Se}_3$   
25  
26 sputtering target (99.999%, ALB Materials, USA) were employed. The experimental  
27  
28 details of thin film deposition are provided elsewhere [8]. No Bragg peaks were  
29  
30 detected in the X-ray diffraction patterns of deposited thin films, data that confirm  
31  
32 their amorphous state.

#### 45 *Mass spectrometry*

46  
47 AXIMA Resonance and AXIMA CFR mass spectrometers, both from Kratos  
48  
49 Analytical Ltd. (Manchester, UK), coupled with a quadrupole ion trap and  
50  
51 time-of-flight detection, were used to record mass spectra in both positive and  
52  
53 negative ion modes. Both instruments were equipped with a nitrogen laser (337 nm),  
54  
55 and the laser repetition rate was set to 5 Hz with a pulse time width of 3 ns.

1 Ten  $\mu\text{L}$  of the  $\text{Sb}_2\text{Se}_3$  powder suspension (described above) was deposited on a  
2  
3 target and then covered with paraffin solution in xylene ( $1\text{ cm}^2$  of parafilm dissolved  
4  
5 in 1 ml xylene).  
6  
7

## 8 **Results and Discussion**

9

10  
11 LDI of different materials was used to generate clusters while mass spectra were  
12  
13 recorded in both positive and negative ionisation modes by using a reflectron mass  
14  
15 analyser. This analysis revealed that a low number of clusters and low-intensity  
16  
17 spectra were produced in the negative ion mode. Therefore, the results obtained in the  
18  
19 positive ion mode are presented.

### 28 *Effect of laser energy on homemade $\text{Sb}_2\text{Se}_3$ polycrystalline material mass spectra*

29

30  
31 The effect of laser energy on intensity of clusters formed is shown in Figure 1. The  
32  
33 high-intensity clusters were observed in the 300-450  $m/z$  range; the intensities  
34  
35 heightened as the laser energy increased. However, some low-intensity clusters were  
36  
37 also observed in the 450-650 mass range (spectra not shown). This data indicates that  
38  
39 the homemade  $\text{Sb}_2\text{Se}_3$  polycrystalline material was rather easy to decompose even at  
40  
41 relatively low laser energy (140 a.u.). Detailed analysis of the homemade  $\text{Sb}_2\text{Se}_3$   
42  
43 polycrystalline material spectra is shown in Fig. S1A. In addition to  $\text{SbSe}_2^+$ ,  $\text{Sb}_2\text{Se}_n^+$   
44  
45 ( $n = 1, 2$ ) and  $\text{Sb}_3\text{Se}_n^+$  ( $n = 1-3$ ) clusters,  $\text{Sb}_m^+$  ( $m = 2-4$ ) clusters were also detected.  
46  
47  
48  
49  
50  
51  
52  
53 Comparison of experimental and theoretical isotopic patterns concerning  $\text{Sb}_3\text{Se}^+$  are  
54  
55 provided in Fig. S1B. Overall, they showed good agreement.

1 *Effect of laser energy on thin film mass spectra*

2  
3 The effect of laser energy on thin film mass spectra (Fig. S2A) was different from  
4 that of homemade Sb<sub>2</sub>Se<sub>3</sub> polycrystalline material. At 140 a.u. laser energy, the cluster  
5 intensities reached their maxima. The mass spectra showed that the thin film was less  
6 stable against pulsed laser irradiation than the homemade Sb<sub>2</sub>Se<sub>3</sub> polycrystalline  
7 material. Further, the thin films were easier to ablate. An example of a thin film mass  
8 spectrum is shown in Figure 2. The thin film mass spectra showed similar clusters to  
9 those formed from the homemade Sb<sub>2</sub>Se<sub>3</sub> polycrystalline material. However, the  
10 Sb<sub>3</sub>Se<sub>3</sub><sup>+</sup>, SbSe<sub>2</sub><sup>+</sup>, Sb<sub>m</sub><sup>+</sup> (*m* = 2-4), Sb<sub>2</sub>Se<sub>n</sub><sup>+</sup> (*n* = 1, 2) and Sb<sub>3</sub>Se<sub>n</sub><sup>+</sup> (*n* = 1, 2) clusters  
11 were not observed. There was good agreement between the theoretical and  
12 experimental isotopic patterns concerning Sb<sub>2</sub>Se<sup>+</sup> cluster (Fig. S2B).

34 *Effect of laser energy on commercial Sb<sub>2</sub>Se<sub>3</sub> polycrystalline material mass spectra*

35  
36 Comparison of mass spectra generated from commercial Sb<sub>2</sub>Se<sub>3</sub> polycrystalline  
37 bulk at different laser energies is shown in Figure 3. Even at low laser energy (120  
38 a.u.), we observed several low-intensity clusters in the *m/z* range over 450. Fig. S3A  
39 shows the result of detailed mass spectra analysis concerning commercial Sb<sub>2</sub>Se<sub>3</sub>  
40 polycrystalline bulk material. Besides SbSe<sub>2</sub><sup>+</sup>, Sb<sub>2</sub>Se<sub>n</sub><sup>+</sup> (*n* = 1-4) and Sb<sub>3</sub>Se<sub>n</sub><sup>+</sup> (*n* = 1-5),  
41 Sb<sub>m</sub><sup>+</sup> (*m* = 3, 4) clusters were also noted. Comparison of experimental and theoretical  
42 isotopic patterns for the Sb<sub>2</sub>Se<sub>2</sub><sup>+</sup> cluster is provided in Fig. S3B; there was good  
43 agreement between the experiment with the theoretical model.

2  
3 *polycrystalline Sb<sub>2</sub>Se<sub>3</sub> material mass spectra*  
4  
5

6 Figure 4 shows thin film, commercial and home-made polycrystalline Sb<sub>2</sub>Se<sub>3</sub>  
7  
8 material mass spectra that were measured using the same laser energy (120 a.u.). At  
9 this laser energy, the order of intensity was thin film, followed by homemade and  
10 finally commercial Sb<sub>2</sub>Se<sub>3</sub> polycrystalline material, data that indicate the stability of  
11 the three materials with respect to the increasing laser pulse. In the homemade  
12 polycrystalline Sb<sub>2</sub>Se<sub>3</sub> material and commercial Sb<sub>2</sub>Se<sub>3</sub> polycrystalline bulk material  
13 mass spectra, the most intensive cluster was Sb<sub>3</sub>Se<sup>+</sup>. Comparatively, in the thin film  
14 mass spectra, the Sb<sub>2</sub>Se<sup>+</sup> cluster was the strongest. The most intense cluster, observed  
15 in the thin film mass spectrum at 140–180 a.u. laser energy, was Sb<sub>3</sub>Se<sup>+</sup>. Additionally,  
16 the commercial Sb<sub>2</sub>Se<sub>3</sub> polycrystalline bulk produced more clusters.

40  
41

42 GO, G or C<sub>60</sub> were previously used as a matrix for SALDI mass spectrometry  
43 [25-27]. We examined whether these materials can increase the intensity of Sb<sub>2</sub>Se<sub>3</sub>  
44 mass spectra. Comparison of mass spectra for commercial Sb<sub>2</sub>Se<sub>3</sub> polycrystalline bulk  
45 and the same material deposited on the surface of GO, C<sub>60</sub> or G at the same laser  
46 energy (120 a.u.) is shown in Figure 6. GO, G and C<sub>60</sub> enhanced the intensity of the

1 enhancing the mass spectra intensity (9-times greater intensity compared to simple  
2  
3 LDI), followed by C<sub>60</sub> and then G.  
4  
5

### 6 *Effect of paraffin*

7  
8

9 Comparison of commercial Sb<sub>2</sub>Se<sub>3</sub> polycrystalline bulk mass spectra with and  
10 without a paraffin cover at 160 a.u. laser energy is shown in Figure 7A, B and C. At  
11 the *m/z* range below 510, the cluster intensities produced solely by Sb<sub>2</sub>Se<sub>3</sub> was higher  
12 than when Sb<sub>2</sub>Se<sub>3</sub> was covered with paraffin. On the contrary, in the *m/z* range over  
13 510, the intensity of the clusters originating in Sb<sub>2</sub>Se<sub>3</sub> covered with paraffin was  
14 higher than that one produced by Sb<sub>2</sub>Se<sub>3</sub> alone. Furthermore, we detected the  
15 formation of new clusters beyond *m/z* 800 (Sb<sub>4</sub>Se<sub>4</sub><sup>+</sup>, Sb<sub>5</sub>Se<sub>3-6</sub><sup>+</sup> and Sb<sub>7</sub>Se<sub>4</sub><sup>+</sup>) from  
16 Sb<sub>2</sub>Se<sub>3</sub> covered with paraffin. Comparison of experimental and theoretical isotopic  
17 patterns for one newly identified Sb<sub>5</sub>Se<sub>6</sub><sup>+</sup> cluster is given in Fig. S4; the data showed  
18 good agreement between the experimental results and theoretical model. The results  
19 obtained indicate that paraffin acts as a protective agent to diminish fragmentation. It  
20 is not easy to explain the effect of paraffines, as it can be very complex. First, because  
21 particles of materials are covered with paraffin layer which is absorbing part of the  
22 laser energy, the fragmentation is diminished. In addition, similarly to those of Ag<sup>+</sup>  
23 adducts with paraffines [28], we observed here the formation of Sb<sub>*m*</sub>Se<sub>*n*</sub><sup>+</sup> cations  
24 adducts with paraffin (C<sub>4</sub>H<sub>10</sub>·Sb<sub>2</sub>Se<sub>3</sub><sup>+</sup> shown in Figure S5 A and C<sub>18</sub>H<sub>38</sub>·Sb<sub>3</sub>Se<sup>+</sup> shown  
25 in Figure S5 B). Such formation of charged adducts can also decrease the  
26 fragmentation. An overview of the Sb<sub>*m*</sub>, Se<sub>*n*</sub> and Sb<sub>*m*</sub>Se<sub>*n*</sub> clusters generated from all  
27 Sb<sub>2</sub>Se<sub>3</sub> forms and Sb:Se mixtures (1:1 or 1:10) [23] is provided in Figure 5.

## Conclusions

LDI with quadrupole ion trap time-of-flight mass spectrometry was used to characterise different  $\text{Sb}_2\text{Se}_3$  forms (commercial or home-made polycrystalline material or amorphous thin films). We showed that this technique is a powerful method to study the formation of binary  $\text{Sb}_m\text{Se}_n$  clusters. Homemade  $\text{Sb}_2\text{Se}_3$  polycrystalline material produced the lowest number of clusters during LDI. Commercial  $\text{Sb}_2\text{Se}_3$  polycrystalline bulk generated a higher number of detected  $\text{Sb}_m\text{Se}_n$  species. The amorphous  $\text{Sb}_2\text{Se}_3$  thin film was easily ablated. We demonstrated that GO, C60 or G are suitable materials for SALDI in order to enhance the mass spectra intensity of the clusters produced from  $\text{Sb}_2\text{Se}_3$  polycrystalline material. With the use of paraffin, some new clusters were detected in the high-mass part of the spectra.

## Acknowledgments

This work was funded with the support from the Czech Science Foundation (Projects No. 18-03823S).

## Figure captions

**Figure 1.** The effect of laser energy on the mass spectra from LDI of homemade  $\text{Sb}_2\text{Se}_3$  polycrystalline material in the 300-500  $m/z$  range in the positive ion mode.

**Figure 2.** Mass spectra from LDI of amorphous  $\text{Sb}_2\text{Se}_3$  thin film in the 200-800  $m/z$  range. The inset shows the magnification of spectra in 500-650  $m/z$  range. Conditions: positive ion mode; 120 a.u. laser energy; \* refers to unidentified clusters.

**Figure 3.** The effect of laser energy on the mass spectra from LDI of commercial  $\text{Sb}_2\text{Se}_3$  polycrystalline bulk in the 300-500  $m/z$  range in positive ion mode.

**Figure 4.** Mass spectra from LDI of commercial and homemade  $\text{Sb}_2\text{Se}_3$  polycrystalline material as well as amorphous  $\text{Sb}_2\text{Se}_3$  thin film in the 300-500 $m/z$  range. Conditions: positive ion mode; 120 a.u. laser energy.

**Figure 5.** Overview of clusters observed by using paraffin and  $\text{Sb}_m\text{Se}_n$  cluster stoichiometry generated from commercial/homemade  $\text{Sb}_2\text{Se}_3$  polycrystalline material, amorphous  $\text{Sb}_2\text{Se}_3$  thin film, and mixtures of antimony with selenium (Sb:Se = 1:1 or 1:10).  New clusters by using paraffin;  Sb:Se = 1:10;  Sb:Se = 1:1;  Thin film;  Commercial polycrystalline  $\text{Sb}_2\text{Se}_3$ ;  Home-made polycrystalline  $\text{Sb}_2\text{Se}_3$ .

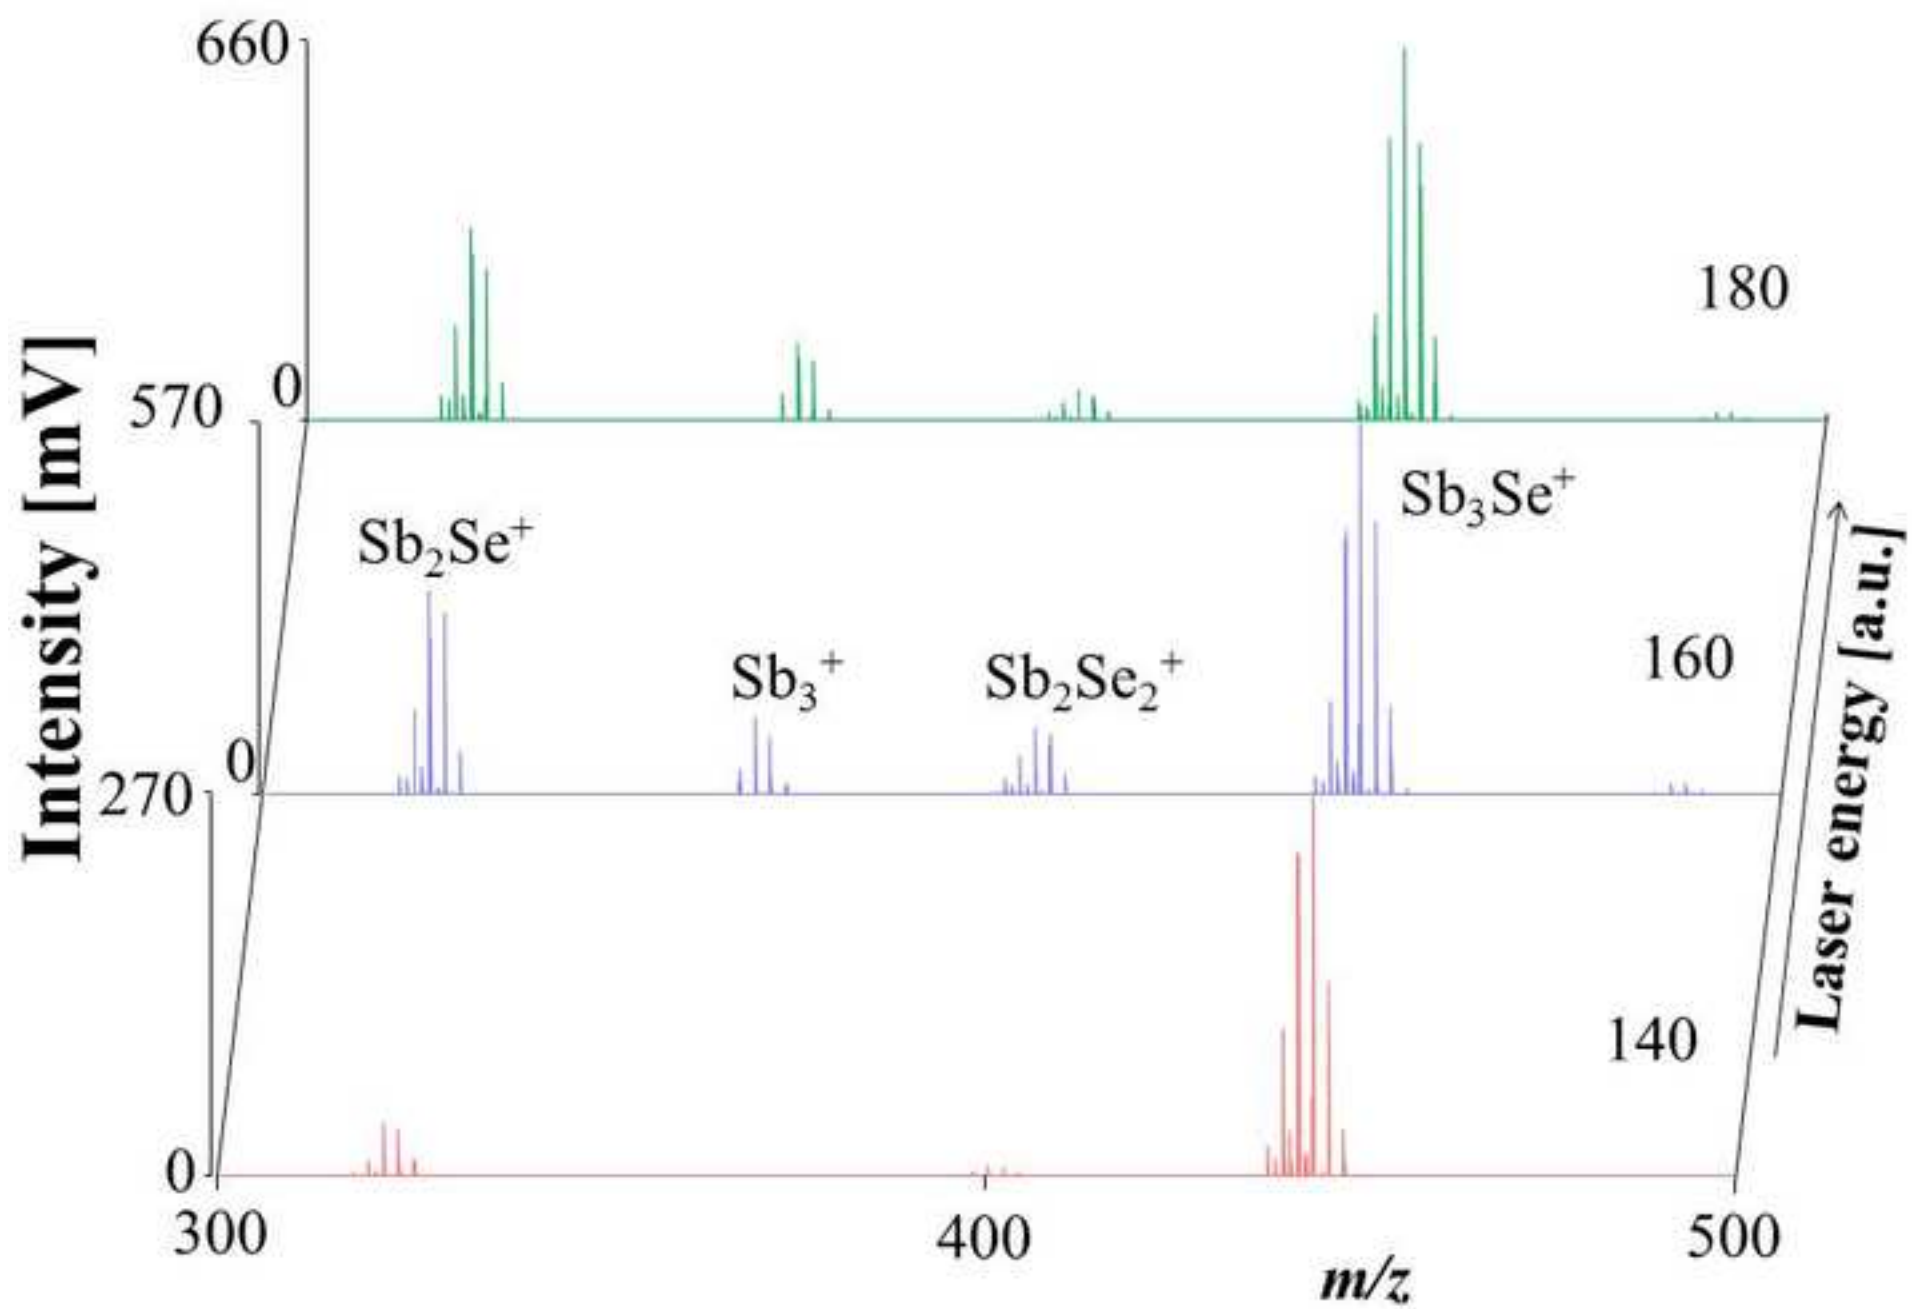

**Figure 6.** Mass spectra from LDI of commercial polycrystalline  $\text{Sb}_2\text{Se}_3$  on the surface of GO,  $\text{C}_{60}$ , G and on a common metal target in the 300-700  $m/z$  range. Conditions: positive ion mode; 120 a.u. laser energy.

**Figure 7A.** Mass spectra from LDI of commercial polycrystalline  $\text{Sb}_2\text{Se}_3$ , and the same sample covered with paraffin, in the 310-510  $m/z$  range. Conditions: positive ion

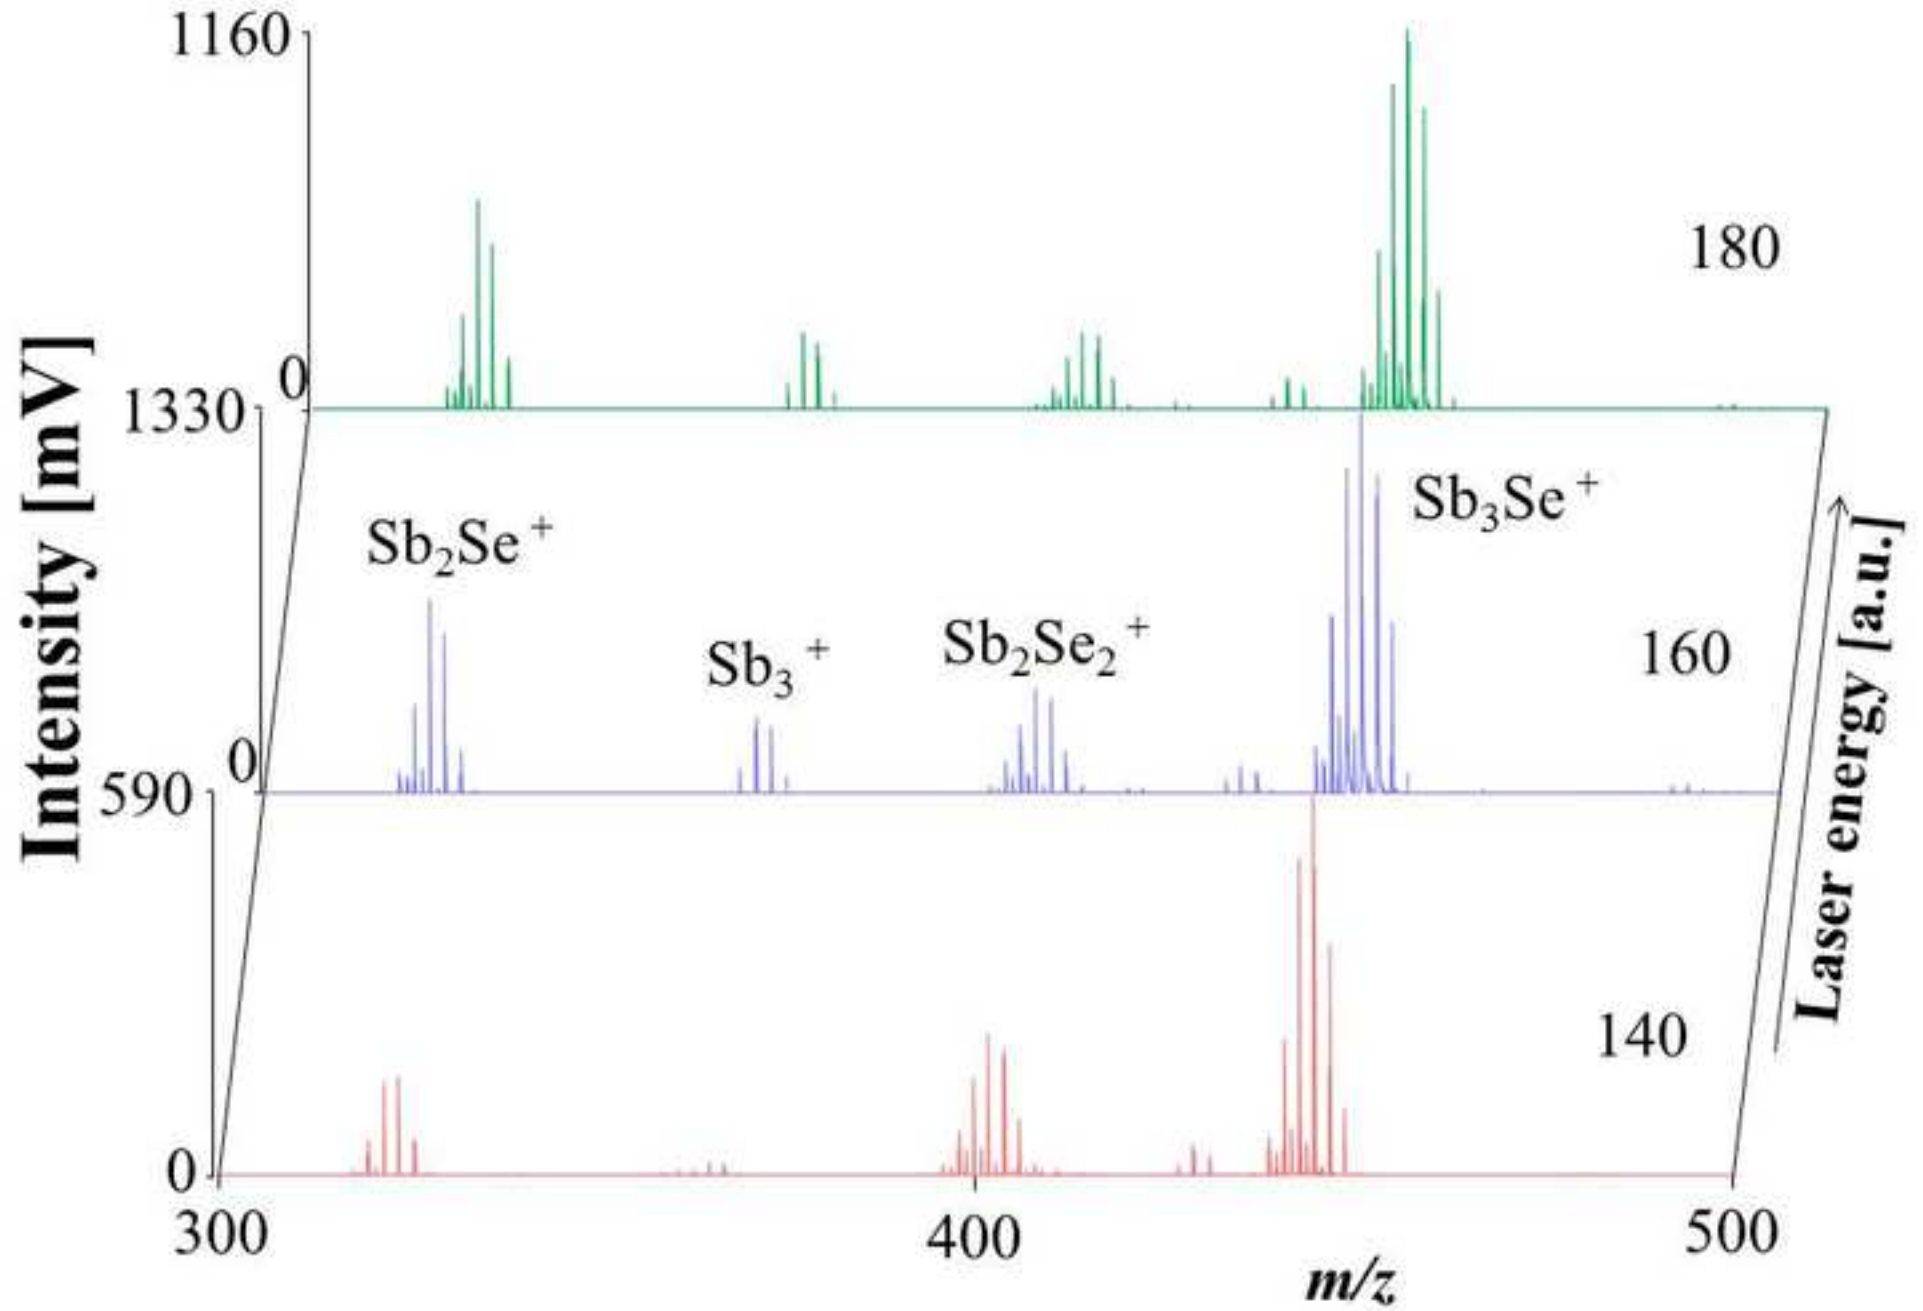

1 mode; 160 a.u. laser energy.  
2

3 **Figure 7B.** Mass spectra from LDI of commercial polycrystalline  $\text{Sb}_2\text{Se}_3$ , and the  
4 same sample covered with paraffin, in the 510-790  $m/z$  range. Conditions: positive ion  
5 mode; 160 a.u. laser energy.
